

Innovation

1. Dependencies

- The required libraries are listed in *requirements.txt*
- When the program is executed, a function *ensure_packages()* in *main.py* verifies if the required libraries are installed, and if not, installs them.

2. Data

- It is assumed that the databases are already saved in the machine and have already been imported
- In case they are not, the folder *db* includes both databases
- It also includes the database schemas
- The [README.md](#) includes instructions to import the databases.

3. Helper functions

Helper functions are created in *my_sql_operations.py* to make the code of the menu functions easier to read, and less repetitive - instead of writing the code inside the menu functions.

List of helper functions:

- *get_valid_comapany_id()*: verify that the company id is valid (integer, positive)
- *get_company_name(company_id)*: given a company_id, get the name of the company
- *get_attendee_name(attendee_id)*: given an attendee_id, get the name of the attendee
- *attendee_exists(attendee_id)*: verify that an attendee_id exists in the database (MySQL).

4. Add new attendee: Neo4j implementation

The menu function to "Add new attendee" adds the attendee to both databases, not just MySQL. Before adding this function, when a new member was created, it was not possible to add connections for that member, because it did not exist in Neo4j.

5. Exceptions

Throughout the code, generic Exceptions are used to catch all errors, also when not required.
